

How optical modules are used in communications

Overview

At the heart of every optical transceiver lie three essential components, often called the “Three Pillars” of optical communication: Laser — generates light. Modulator — encodes data onto the light. Whether in 5G base stations, hyperscale data centers, or long-haul telecom networks, these modules convert electrical signals into optical ones — and back again — to ensure fast, stable, and. As an essential component of optical fiber communication, optical modules are optoelectronic devices that facilitate the conversion between optical and electrical signals during the transmission process. They are used in fiber optic communication systems to transmit data over long distances with minimal loss and interference. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside.
