

Monochromator of an atomic spectrophotometer

Overview

The monochromator comprises a dispersive element, an entrance slit and mirrors to create a parallel beam similar to sunlight, and an exit slit and mirrors to extract the monochromatic light. The prism and diffraction grating are typical dispersive elements. Learn what they are, how they work, and their uses. Justin Tom received his PhD in chemistry in 2018 under the supervision of Professor Heather Andreas at Dalhousie University. He is particularly interested in chemical analysis, surface. Monochromator in an x-ray beamline at the Advanced Photon Source, Argonne National Laboratory. This precise spectral. Monochromators are optical devices designed to isolate a specific wavelength of light from a broader spectrum, playing a crucial role in various spectroscopic techniques, including atomic spectroscopy.

Monochromator

A monochromator can use either the phenomenon of optical dispersion in a prism, or that of diffraction using a diffraction grating, to spatially separate the colors of light. It usually has a mechanism for directing the selected color to an exit slit. Usually the grating or the prism is used in a reflective mode. A reflective prism is made by making a right triangle prism (typically, half of an equilateral prism) with one side mirrored. T...
